

Intro to JUnit

References:

Dr. Ghosh's slides based on <http://www.junit.org/>
 Paul Ammann & Jeff Offutt from <http://www.cs.gmu.edu/~offutt/softwaretest/>

What is JUnit?

- Open source Java testing framework used to write and run repeatable automated tests
- JUnit is open source (junit.org)
- A structure for writing test drivers
- JUnit features include:
 - Assertions for testing expected results
 - Test fixtures for sharing common test data
 - Test suites for easily organizing and running tests
 - Graphical and textual test runners
- JUnit is widely used in industry
- JUnit can be used as stand alone Java programs (from the command line) or within an IDE such as Eclipse

2

JUnit Tests

- JUnit can be used to test ...
 - ... an entire object
 - ... part of an object – a method or some interacting methods
 - ... interaction between several objects
- It is primarily for unit and integration testing, not system testing
- Each test is embedded into one test method
- A test class contains one or more test methods
- Test classes include :
 - A test runner to run the tests (main())
 - A collection of test methods
 - Methods to set up the state before and update the state after each test and before and after all tests
- Get started at junit.org

3

Using JUnit

- Integrated with Eclipse – several advantages
 - Environment variables set up automatically
 - Execution tied with the Eclipse debugger
 - Test driver skeleton generated – just fill in test cases

4

Writing test cases in JUnit (Eclipse)

- Right-click on the ProjectWithJUnit title
- Select **New -> Other**
- Expand the "Java" selection, and choose **JUnit**.
- On the right column of the dialog, choose **Test Case**
- Click **Next**.
- Run the JUnit file as an application/debug mode.

5

Steps for using JUnit

- Simple framework to write repeatable tests.
- Write a test:
 - Import `junit.framework.*`
 - Extends class `junit.framework.TestCase`
 - Modify the following methods:
 - `protected void setUp()` – set up the fixture of the test.
 - `protected void tearDown()` – release resources allocated in `setUp()`.
- Write test methods for the test case (method name should begin with `test`):

```
public void testMoney(){...}
```

 - Use the following method for test:
 - `assertEquals(Object, Object)` – check if two objects are equal
 - `assertTrue(boolean)` – check if boolean expression is true
- Run the test using three different test runners:
 - `java junit.awtui.TestRunner ClassName`
 - `java junit.swingui.TestRunner ClassName`
 - `java junit.textui.TestRunner ClassName`

6

Example JUnit Test Case

```

public class Calc
{
    public long add (int a, int b)
    {
        return a + b;
    }
}

import org.junit.Test;
import static org.junit.Assert.*;
public class calcTest
{
    private Calc calc;
    @Test public void testAdd()
    {
        calc = new Calc ();
        assertEquals ((long) 5, calc.add (2, 3));
    }
}

```

AllTests

```

import org.junit.runner.RunWith;
import org.junit.runners.Suite;
import junit.framework.JUnit4TestAdapter;

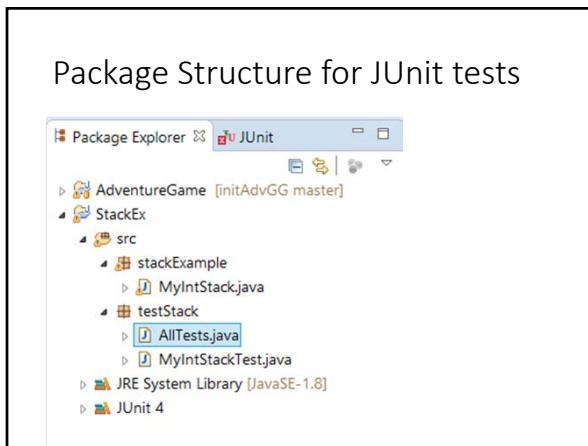

// This section declares all of the test classes in the program.
@RunWith (Suite.class)
@Suite.SuiteClasses ({ StackTest.class }) // Add test classes here.

public class AllTests
{
    // Execution begins at main(). In this test class, we will execute
    // a text test runner that will tell you if any of your tests fail.
    public static void main (String[] args)
    {
        junit.textui.TestRunner.run (suite());
    }

    // The suite() method is helpful when using JUnit 3 Test Runners or Ant.
    public static junit.framework.Test suite()
    {
        return new JUnit4TestAdapter (AllTests.class);
    }
}

```

Class under test

MyIntStack.java

```

package stackExample;
import java.util.*;

public class MyIntStack extends Stack<Integer> {
    public Stack<Integer> makeStack() {
        return new Stack<Integer>();
    }

    public static void main(String args[]) {
    }
}

```

Test Code

MyIntStackTest.java

```

package testStack;
import stackExample.MyIntStack;
import static org.junit.Assert.*;
import org.junit.Test;

public class MyIntStackTest {
    private MyIntStack intStack = new MyIntStack();

    @Test
    public void testEmptyMyIntStack() {
        assertEquals(true, intStack.empty());
        assertEquals(true, intStack.isEmpty());
    }

    @Test
    public void testPushNullOnMyIntStack() {
        intStack.push(null);
        assertEquals(true, intStack.empty());
    }

    @Test
    public void testPopEmptyMyIntStack() {
        intStack.push(null);
        intStack.pop();
        assertEquals(true, intStack.empty());
    }
}

```

All Tests – test driver

AllTests.java

```

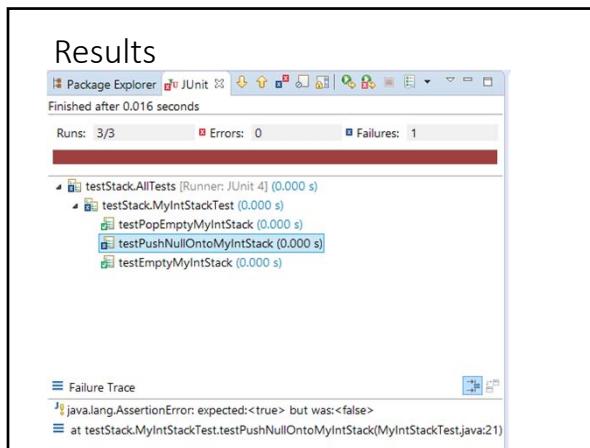

package testStack;
import org.junit.runner.RunWith;
import org.junit.runners.Suite;
import org.junit.runners.Suite.SuiteClasses;
import junit.framework.*;

@RunWith (Suite.class)
@Suite.SuiteClasses ({ MyIntStackTest.class })

public class AllTests
{
    public static void main (String[] args)
    {
        junit.textui.TestRunner.run (suite());
    }

    // The suite() method is helpful when using
    // JUnit 3 Test Runners or Ant.
    public static junit.framework.Test suite()
    {
        return new JUnit4TestAdapter (AllTests.class);
    }
}

```

What to do and not to do

- Do's:
 - Create new objects using constructors that are known to be correct.
 - Use the equals() method if it is known to be correct.
- Don'ts:
 - Suppose you want to test method foo(). **DO NOT** use methods bar() and foo() in the same test case if bar() is not known to be correct.
 - If the test failed, you don't know if it is because of foo() or bar().
