Opening Problem

Find the sum of integers from 1 to 10, from 20 to 30, and from 35 to 45, respectively.

Problem

```java
int sum = 0;
for (int i = 1; i <= 10; i++)
    sum += i;
System.out.println("Sum from 1 to 10 is " + sum);

sum = 0;
for (int i = 20; i <= 30; i++)
    sum += i;
System.out.println("Sum from 20 to 30 is " + sum);

sum = 0;
for (int i = 35; i <= 45; i++)
    sum += i;
System.out.println("Sum from 35 to 45 is " + sum);
```

Solution

```java
public static int sum(int i1, int i2) {
    int sum = 0;
    for (int i = i1; i <= i2; i++)
        sum += i;
    return sum;
}

public static void main(String[] args) {
    System.out.println("Sum from 1 to 10 is " + sum(1, 10));
    System.out.println("Sum from 20 to 30 is " + sum(20, 30));
    System.out.println("Sum from 35 to 45 is " + sum(35, 45));
}
```

- To design and implement methods using stepwise refinement (§6.10).
Defining Methods

A method is a collection of statements that are grouped together to perform an operation.

```java
public static int max(int num1, int num2) {
    int result;
    if (num1 > num2)
        result = num1;
    else
        result = num2;
    return result;
}
```

Method Signature

Method signature is the combination of the method name and the parameter list.

Formal Parameters

The variables defined in the method header are known as formal parameters.

Actual Parameters

When a method is invoked, you pass a value to the parameter. This value is referred to as actual parameter or argument.

Return Value Type

A method may return a value. The return value type is the data type of the value the method returns. If the method does not return a value, the return value type is the keyword void. For example, the return value type in the main method is void.
Calling Methods

Testing the max method

This program demonstrates calling a method max to return the largest of the int values.

```
public static int max(int num1, int num2) {
    int result;
    if (num1 > num2) {
        result = num1;
    } else {
        result = num2;
    }
    return result;
}
```

```
public static void main(String[] args) {
    int i = 5;
    int j = 2;
    int k = max(i, j);
    System.out.println("The maximum between "+ i + " and " + j + " is " + k);
}
```
```java
public static void main(String[] args) {
    int i = 5;
    int j = 2;
    int k = max(i, j);
    System.out.println(
        "The maximum between " + i + 
        " and " + j + " is " + k);
}

public static int max(int num1, int num2) {
    int result;
    if (num1 > num2)
        result = num1;
    else
        result = num2;
    return result;
}
```

return max(i, j) and assign the return value to k.

Execute the print statement.

return result, which is 5.

(result > num2) is true since num1 is 5 and num2 is 2.

result is now 5.

Numerical print statements: The maximum between 5 and 2 is 5.
CAUTION
A return statement is required for a value-returning method. The method shown below in (a) is logically correct, but it has a compilation error because the Java compiler thinks it possible that this method does not return any value.

```java
public static int sign(int n) {
    if (n > 0)
        return 1;
    else if (n == 0)
        return 0;
    else if (n < 0)
        return -1;
}
```

To fix this problem, delete if (n < 0) in (a), so that the compiler will see a return statement to be reached regardless of how the if statement is evaluated.

Reuse Methods from Other Classes
NOTE: One of the benefits of methods is for reuse. The max method can be invoked from any class besides TestMax. If you create a new class Test, you can invoke the max method using ClassName.methodName (e.g., TestMax.max).

```java
public static void main(String[] args) {
    int i = 5;
    int j = 2;
    int k = max(i, j);
    System.out.println("The maximum between " + i + " and " + j + " is " + k);
}
```

```java
public static int max(int num1, int num2) {
    int result;
    if (num1 > num2)
        result = num1;
    else
        result = num2;
    return result;
}
```

void Method Example

This type of method does not return a value. The method performs some actions.

```java
public static void main(String[] args) {
    int i = 5;
    int j = 2;
    int k = max(i, j);
    System.out.println("The maximum between " + i + " and " + j + " is " + k);
}

public static int max(int num1, int num2) {
    int result;
    if (num1 > num2) {
        result = num1;
    } else {
        result = num2;
    }
    return result;
}
```

Passing Parameters

```java
public static void nPrintln(String message, int n) {
    for (int i = 0; i < n; i++)
        System.out.println(message);
}
```

Pass by Value

This program demonstrates passing values to the methods.

```java
public static void nPrintln(String message, int n) {
    for (int i = 0; i < n; i++)
        System.out.println(message);
}
```

Case Study: Converting Hexadecimals to Decimals

Write a method that converts a hexadecimal number into a decimal number.

ABCD =>
A*16^3 + B*16^2 + C*16^1 + D*16^0
= ((A*16 + B)*16 + C)*16 + D
= ((10*16 + 11)*16 + 12)*16 + 13 = ?

Overloading Methods

Overloading the max Method

public static double max(double num1, double num2) {
    if (num1 > num2)
        return num1;
    else
        return num2;
}

public static double max(int num1, double num2) {
    if (num1 > num2)
        return num1;
    else
        return num2;
}

public static double max(double num1, int num2) {
    if (num1 > num2)
        return num1;
    else
        return num2;
}

Ambiguous Invocation

Sometimes there may be two or more possible matches for an invocation of a method, but the compiler cannot determine the most specific match. This is referred to as ambiguous invocation. Ambiguous invocation is a compile error.

public class AmbiguousOverloading {
    public static void main(String[] args) {
        System.out.println(max(1, 2));
    }

    public static double max(double num1, double num2) {
        if (num1 > num2)
            return num1;
        else
            return num2;
    }

    public static double max(int num1, double num2) {
        if (num1 > num2)
            return num1;
        else
            return num2;
    }

    public static double max(double num1, int num2) {
        if (num1 > num2)
            return num1;
        else
            return num2;
    }
}

Scope of Local Variables

A local variable: a variable defined inside a method.
Scope: the part of the program where the variable can be referenced.
The scope of a local variable starts from its declaration and continues to the end of the block that contains the variable. A local variable must be declared before it can be used.

Scope of Local Variables, cont.
You can declare a local variable with the same name multiple times in different non-nesting blocks in a method, but you cannot declare a local variable twice in nested blocks.

Scope of Local Variables, cont.
A variable declared in the initial action part of a `for` loop header has its scope in the entire loop. But a variable declared inside a `for` loop body has its scope limited in the loop body from its declaration and to the end of the block that contains the variable.

```java
public static void method1() {
    for (int i = 1; i < 10; i++) {
        int j;
    }
}
```

The scope of `j` is limited to the `for` loop body.

```java
public static void method2() {
    int i = 1;
    int sum = 0;
    for (int i = 1; i < 10; i++) {
        sum += i;
    }
}
```

The scope of `i` is limited to the `for` loop body.

Scope of Local Variables, cont.
// Fine with no errors
```java
public static void correctMethod() {
    int x = 1;
    int y = 1;
    // i is declared
    for (int i = 1; i < 10; i++) {
        x += i;
    }
    // i is declared again
    for (int i = 1; i < 10; i++) {
        y += i;
    }
}
```

Scope of Local Variables, cont.
// With errors
```java
public static void incorrectMethod() {
    int x = 1;
    int y = 1;
    // i is declared
    for (int i = 1; i < 10; i++) {
        int x = 0;
        x += i;
    }
}
```

Method Abstraction
You can think of the method body as a black box that contains the detailed implementation for the method.

```
Method Header

```

Black Box
Benefits of Methods

- Write a method once and reuse it anywhere.
- Information hiding. Hide the implementation from the user.
- Reduce complexity.

Case Study: Generating Random Characters

Computer programs process numerical data and characters. You have seen many examples that involve numerical data. It is also important to understand characters and how to process them.

As introduced in Section 2.9, each character has a unique Unicode between 0 and FFFF in hexadecimal (65535 in decimal). To generate a random character is to generate a random integer between 0 and 65535 using the following expression: (note that since 0 <= Math.random() < 1.0, you have to add 1 to 65535.)

\[(\text{int})(\text{Math.random()} \times (65535 + 1))\]

Case Study: Generating Random Characters, cont.

Now let us consider how to generate a random lowercase letter. The Unicode for lowercase letters are consecutive integers starting from the Unicode for 'a', then for 'b', 'c', ..., and 'z'. The Unicode for 'a' is

\[(\text{int}'a')\]

So, a random integer between (int)'a' and (int)'z' is

\[(\text{int})(\text{int}'a' + \text{Math.random()} \times ((\text{int}'z' - (\text{int}'a' + 1)))\]

Case Study: Generating Random Characters, cont.

As discussed in Chapter 2., all numeric operators can be applied to the char operands. The char operand is cast into a number if the other operand is a number or a character. So, the preceding expression can be simplified as follows:

'a' + Math.random() \times (z' - a' + 1)

So a random lowercase letter is

(char)(a' + Math.random() \times (z' - a' + 1))
The RandomCharacter Class

// RandomCharacter.java: Generate random characters
public class RandomCharacter {
    public static char getRandomCharacter(char ch1, char ch2) {
        return (char)(ch1 + Math.random() * (ch2 - ch1 + 1));
    }

    public static char getRandomLowerCaseLetter() {
        return getRandomCharacter('a', 'z');
    }

    public static char getRandomUpperCaseLetter() {
        return getRandomCharacter('A', 'Z');
    }

    public static char getRandomDigitCharacter() {
        return getRandomCharacter('0', '9');
    }

    public static char getRandomCharacter() {
        return getRandomCharacter('\u0000', '\uFFFF');
    }
}

Stepwise Refinement (Optional)

The concept of method abstraction can be applied to the process of developing programs. When writing a large program, you can use the “divide and conquer” strategy, also known as stepwise refinement, to decompose it into subproblems. The subproblems can be further decomposed into smaller, more manageable problems.

PrintCalendar Case Study

Let us use the PrintCalendar example to demonstrate the stepwise refinement approach.

Design Diagram
Implementation: Top-Down

Top-down approach is to implement one method in the structure chart at a time from the top to the bottom. Stubs can be used for the methods waiting to be implemented. A stub is a simple but incomplete version of a method. The use of stubs enables you to test invoking the method from a caller. Implement the main method first and then use a stub for the printMonth method. For example, let printMonth display the year and the month in the stub. Thus, your program may begin like this:

A Skeleton for printCalendar

Implementation: Bottom-Up

Bottom-up approach is to implement one method in the structure chart at a time from the bottom to the top. For each method implemented, write a test program to test it. Both top-down and bottom-up methods are fine. Both approaches implement the methods incrementally and help to isolate programming errors and makes debugging easy. Sometimes, they can be used together.
Benefits of Stepwise Refinement

- Simpler Program
- Reusing Methods
- Easier Developing, Debugging, and Testing
- Better Facilitating Teamwork
