**Meet Meggy Junior!**

Meggy Jr RGB is a handheld platform for developing your own pixel-scale video games. Meggy Jr has an 8x8 LED matrix display, six comfy buttons, a noise making device, and even 8 extra LEDs for whatever you like. Meggy Jr can run on batteries or external power. Meggy Jr is fast, programmable, open source and hackable.

**Meet Meggy Junior!**

Meggy Jr is here to play.

**CPU:**
An ATmega168, which is a type of AVR microcontroller. (You can also use an '88 or '328.)

**USB-TTL interface:**
If you have a USB-TTL cable, you can use this port to program or communicate with Meggy Jr, much like you would with an Arduino.

**Auxiliary LEDs:**
Eight extra LEDs-- not in the matrix-- that can be used (for example) to indicate lives, score, ammo, or level.

**8x8 RGB LED Matrix Display:**
That's 192 LEDs all together. The LED matrix is socketed so that you can pull it out if necessary.

**Buttons:**
Six big, comfy 12 mm pushbutton switches with molded key caps.

**Lo-Fi speaker:**
Bzzt! Bleep! Bloop!

**Printed circuit board:**
White with black printing.
Outline: 5.300” x 2.800”
(About 13.5 x 7.1 cm)

(Also: 16 MHz Crystal oscillator, ISP programming interface, AAA battery box, a place to put a power jack, power selector jumper, extra holes to access ADC inputs of microcontroller and more.)

**LED driver chips & transistors:**
These components manage the current needed to drive all those LEDs. Hidden underneath the LED matrix display.

**Reset Button:**
Optional but included with the kit. Push to reboot.

**Mounting holes:**
While these are normally used for mounting Meggy Jr in a set of cool handles, you can actually attach Meggy Jr to almost anything. (Robo-Meggy Jr, anyone?)
STEP 1: Tool Checklist

**Essential tools:** Needed to build the kit:

1. **Soldering iron + solder**
   A basic soldering iron meant for electronics, with a reasonably fine point tip. We recommend one of this design—a "pencil shape" soldering iron (not gun!) with a base that holds the iron and a wet sponge. A tip in good condition (a "tinned" tip) should get shiny when hot—able to melt and wet to solder.

   While you don’t need an expensive one, the iron can make a big difference in the time needed to build the kit. (Seriously. If you use one that is old and busted, or a $10 radio shack iron, or that thing from the dollar store, please expect to spend at least twice as long soldering!)

   Our recommendation for a low-cost iron: model WLC100 by Weller, about $40.

   You’ll also need some solder. Thin rosin-core solder (roughly .020 - .040" in diameter) is the most common and best choice for this application. Either standard (lead-bearing) or newer “lead free” solder types will both work just fine.

2. **Angle flush cutters**
   For clipping loose wire ends close to the circuit board.

   e.g., Sears Craftsman

3. **Small fine-point plier set**
   For various nimble-fingered tasks.

   e.g., Sears Craftsman. The Sears Craftsman #45671 mini-plier set includes both the clippers and pliers shown here.

4. **AAA batteries (3)**
   (Alkaline recommended.)

**Optional but recommended:**

1. **Resistor lead forming tool**
   Allows fast, neat bending of resistor leads.

   This one is Speedy Bend 801, Mouser part #5166-801 (~$8)

2. **Wire strippers**
   There’s one place near the end of the build where it’s convenient (but optional) to shorten and strip two wires. This model is our favorite: Ideal T-Stripper #45-121 (the 14-24 gauge size).

3. **Hot Glue Gun**
   Just one dab of glue for strain relief, near the end.

And for Programming...

1. **USB-TTL Cable**
   FTDI model TTL-232R or equivalent. A “smart” converter cable with a USB interface chip inside. One end hooks up to your USB port, the other to Meggy Jr. This allows you to program Meggy Jr through the Arduino development environment (http://arduino.cc/).

   Alternately, Meggy Jr can be programmed through an AVR ISP programmer, like the USBtinyISP.

2. **Computer, Internet access, USB port...**
   All of the software that you’ll need is available online for free. You’ll need a reasonably recent vintage computer (Mac, Windows, or Linux) and internet access.

   Get started here: http://www.evilmadscientist.com/go/meggyjr

</table>

For the sake of clarity, kit contents are sorted into a few different bags of parts. Most of the parts are labeled by their line item number that appears on the from the bill of materials ( ). (While it can create some interesting mystery, we do not actually suggest that you dump all the parts out into a big pile. Just take them out of their bags as needed.)

The first part on our list is #1, the Meggy Jr printed circuit board:

This table lists the kit contents, roughly in the order of assembly. It is not (repeat: not) a set of build instructions! There are a few places where the operations and their order is important for (possibly) subtle reasons. Please follow along as we go through the steps, even if you are an expert.

In most of the remaining steps, we'll be adding components to this circuit board.
**STEP 3: Adding first components... (and how to do it!)**

**Implied procedure** for adding electronic components:

1. Bend the leads of components as needed.
   (Resistors need to be bent, most others parts do not. Optionally use lead forming tool shown in Step 1.)

2. Insert each component into the circuit board, from the top, at its given location. Push it flush to the board.
   (Resistors are *unpolarized*; they can go in *either* way.)

3. On the back side, gently bend the leads out at 45° to hold components in place while you solder.

4. One at a time, from the back side, solder the leads of the component to the circuit board.
   - Your tip should be shiny (tinned). If not, melt some fresh solder against it and wipe clean on a wet sponge.
   - Place the solder against the joint that you wish to connect.
   - Touch the iron to the solder and joint for about one second. Count it out: "one thousand one."
   - The solder should melt to the joint and leave a shiny wet-looking joint. If not, let it cool and try again.

5. Clip off extra leads on back side, flush to the board.
   (But not so flush that you're clipping the board itself.)

---

**Part #2** is a 1 kilo-ohm resistor
(Color code: Brown-Black-Red-Gold)

Add two of these resistors to the circuit board, in locations **R1** and **R2**.

---

**Meggy Jr RGB**

---
STEP 4: The rest of the resistors, and transistor prep

Part #3 is a 100 ohm resistor
(Color code: Brown-Black-Brown-Gold)
Add one resistor to the circuit board, in location R3.

Part #4 is a 10 kilo-ohm resistor
(Color code: Brown-Black-Orange-Gold)
Also: it’s the one smaller-size resistor!
Add one resistor to the circuit board, in location R4.

Part #5 is a 620 ohm resistor
(Color code: Blue-Red-Brown-Gold)
Add 9 resistors to the circuit board, in locations RB0 through RB8.

Part #6 is a transistor
You’ll need nine, in locations Q0 through Q8.
They need a little prep before soldering.
(Note: the kit includes one extra transistor.)

1. Orient a transistor with the flat side (the side with the writing) facing you. Grip it, very close to the top, with your fine point pliers as shown.
(Sturdy tweezers can also be used for this.)

2. Bend the leads up towards you by 90°, so that they stick out straight. Then, spread the leads out slightly so that they aren’t quite so close together.
(Gripping them with the pliers while doing this lets you make a tight bend with only minimal stress on the device.)
**STEP 5: Add transistors and prep right-angle headers**

Now add the transistors to the board!

In locations Q0 through Q8, insert the transistors with the flat side down, all the way flush to the board. The orientation is important: The flat side should be over the dotted-line square that contains the component name. Solder in place all three pins of each transistor and trim their leads.

---

**Part #7 is a 10-pin right-angle header**

This “break-away” header splits into the parts that go into locations J2 and J3.

---

1. Using small pliers, grip the first three positions of the header. Hold the rest of the pins—tight—with your fingers.

2. Holding steady the pins between your fingers, rock the pliers back and forth to split the header in two. It will either split into two parts as 6/4 pins or 7/3 pins. (Either is okay.)

3. Trim the excess pin away to end up with a 3-pin header and a 6-pin header, which we'll use in the next step.
**STEP 6: ADD RIGHT-ANGLE HEADERS AND SPEAKER**

**Add the right-angle headers to the board.**

Add the 6-pin header in location J2, and the 3-pin header in location J3. The pins fit loosely in the holes. It may be helpful to tack them in place with a piece of tape (touching the plastic part only) while you solder the first pin.

Check after soldering the first pin to make sure that the header pins are level to the board.

---

**Part #8 is a magnetic speaker/buzzer.**

Add this component to location L1 in the upper left corner of the circuit board.

---

**Part #9 is an LED driver chip.**

(Type STP16DP05B1R or compatible)

There are two of these, that go in locations U2, U3.

First, figure out which way is which on the chips.

The most important feature to notice on the chips is the “half-moon” indentation at one end of the chip. This is the polarity marker. (Other markings on the chips may vary.)

---

The speaker has a marking on the top (“+”) to indicate its orientation. There are also corresponding marks on the bottom side for + and -.

Insert the speaker into the board with the “+” pin into the matching “+” labeled hole on the circuit board and solder it in place.
STEP 7: Add the Chips

Now add the LED driver chips, **U2, U3**.

Orientation—**very important**—Half-moon end of chip matches that of the drawing on the circuit board.

The chips should easily slip into the board. If necessary, bend the leads of the chip to straight up and down before inserting the chip. Do not bend them by hand; bend all pins on one side at a time by pushing them against a hard flat surface.

From end of chip:  
- **no.**  
- **YES!**

Press the chips flush onto the circuit board and solder them in place. You will be soldering directly to the pins of the chips, so try to keep your soldering time to about one second per pin.  
(See also soldering tips in Step 3.)

To keep the chips in place while you solder, slightly bend out the corner pins on the back side of the circuit board.

Part #10 is the microcontroller.

Add the pre-programmed ATmega168 microcontroller in location **U1**. Again, pay close attention to the orientation of the device on the board, matching the half-moon end of the chip to the half-moon shape on the printed circuit board.

In particular, note that this chip is **upside down** with respect to the other two chips— the label “U1” is written upside down to emphasize that point.

As with the last chips, press this one flush onto the board and solder it into place.
**STEP 8: Crystals & Caps**

**Part #11 is an 18 pF ceramic capacitor**

Add two capacitors at locations C7 and C8.

(Like resistors, you can put these in either way.)

Note: The labels on these tiny capacitors are approximately invisibly small-- they are the two little caps that are bagged and/or taped together.

**Part #12 is a 16 MHz crystal oscillator**

A shiny steel can. Install this component in location XTL on the circuit board, flush to the board as usual. The two pins go in the outer two holes of location XTL; you can ignore the middle hole. (Orientation: Either way.)

Note: The side of the crystal oscillator may (or may not) rub up against one pin of the microcontroller (U1). This is not a concern in either case.

**Part #13 is a 1200 µF capacitor**

After a little prep, this component will be installed in location C3.

Orientation matters: the negative side of the capacitor is marked with a broad white stripe.

1. Orient the capacitor with the negative side (the side with the broad stripe) facing you. Grip it, near the top, with your fine point pliers as shown.

2. Bend the leads down 90°, so that they stick straight down.

(Gripping them with the pliers while bending lets you make a tight bend with only minimal stress on the device.)
STEP 9: The Capacitors Strike Back

Add the properly bent capacitor in location **C3**.

The capacitor is larger than the outline of the drawing on the circuit board but will still fit in place. Be sure that the negative side of the capacitor goes to the side of the side marked “-“ on the circuit board.

Push the capacitor flush to the circuit board and solder it in place.

**Part #14** is a 0.1 µF ceramic capacitor

Add five of these capacitors, in locations **C1, C2, C4, C5 and C6**. (Orientation: Either way.)

Again, the labels are tiny. If your eyes are very good, you might be able to make out the legend “104” on these. But no need. :)

Note: **C4** is almost underneath C3; you can bend it out a little bit for a better fit if needed.
**STEP 10: Leetle LEDs & Optional ISP connector**

**Part #15** is a tiny 3mm diffused yellow LED

We’re adding 8 of these LEDs to the board, in locations D0 through D7.

The orientation matters. Each LED has a flat facet on the plastic top on one side. That side also has a short lead. This side of the LED goes into the round hole.

The other side has a long lead and goes to the square hole.

---

Like so: Long lead (first!) into the square hole.

Then push the LEDs flush to the board and solder them in place.

---

**Part #16** is a 6-pin dual inline header

>>An OPTIONAL PART that most users SHOULD NOT INSTALL.

(It’s an auxiliary programming port for use with AVR ISP programmers. Do not add this to your circuit board unless you already have and plan to use an ISP programmer. It is not needed for using Meggy Jr or for programming through a USB-TTL cable.)

If you’re really sure that you need it, add it on the back side of the circuit board, underneath marked location J1.
STEP 11: Socketing the LED Matrix Display

Parts #17 & #18: LED display and its sockets

The 8x8 LED matrix display sits in a set of socket strips on the circuit board at location U4. It has lots of pins, so it can (potentially) be difficult to insert into a socket. To make it much easier, we'll instead add the sockets to the display and do so in small segments.

1. Start with the LED matrix display upside down. To avoid scratching the black paint on the front, set it on a clean soft surface like a piece of paper. (This page will do nicely!)

2. With (a bit of wiggle and) firm even pressure, slide one of the four socket strips onto the LED display pins as shown.

The 10-pin socket strip goes over 8 pins of the display, leaving two pins hanging off the edge. Also, it should go as far down onto the pins as shown—it should not sit near the top of the pins.

If the LED display pins are initially bent a bit away from vertical, you may need to gently adjust to them to help the socket strip fit on neatly.

3. Use small pliers to gently break off the two extra pins hanging off the edge.

4. Add the other three socket strips to the LED display the same way. This completes the socket assembly; next, we'll add it to the board!
STEP 12: Add the Socketed LED Matrix Display and the Button Switches

Add the socketed display in location **U4**.

**U4**, Oriented with label **HERE**:

Set the socketed display into its position (U4), with the labeled edge on the left side as shown.

Position the display flat, resting gently (near the top) on large capacitor C3. The pins of the socket should barely extend past the back side of the circuit board.

Turn it up side down onto a flat surface. Holding the circuit board **LEVEL**—judging by how far the different pins stick through—first solder one of the corner pins, to tack the display in place. Verify from the top side that the LED display is level before proceeding to solder the rest of the pins.

Part **#19** is a small tactile button switch.

This is an **OPTIONAL PART** that is not required (but might be nice).

If installed, the Meggy Jr RGB will be reset (i.e., rebooted) when you push this button. If you want it, **snap** it into location **S1** (Reset), and solder all four pins from the back side.

Part **#20** is a large tactile button switch.

Six of these snap into locations **b0** through **b5**: the gameplay button locations. Each has six pins: four metal pins and two plastic pins that help keep it in place.

Be careful! When this snaps into the board, those metal pins can poke you, so don’t put your fingers right where it will snap through. (And solder the four metal pins, but not the two plastic ones.)

After the socket pins are soldered in place, the LED display can— if necessary—be removed (with a careful and firm rocking motion) and put back in place.
**Part #21** is a 3 x AAA battery box w/ switch

The wires from the battery box go to the holes that are (on the top of the board) labeled VCC_IN (red wire) and GND_IN (black wire).

They enter the board from the back side (where those two holes are labeled “+” and “-”) and are soldered on the top side.

The wires supplied are longer than necessary, given the position that the battery box sits in (see photo). But, if you happen to have a pair of wire strippers handy, you can cut the wires a bit shorter before attaching them. (See also step 16.)

---

**Part #22** is a small header jumper

Connect the jumper over the left two pins of J3 when running Meggy Jr off of batteries, or over the two right pins to draw power from an external source like an ac adapter.

---

After soldering the wires, it is recommended to cover the point where they enter the board with a small glob of hot glue, to provide strain relief.

---

**Note:** J4 is a location to install a power jack on the reverse side of the board. Your ac adapter should output for 4.5 - 5 V dc, regulated, center-positive, with at least 600 mA capacity.
STEP 14: Button Caps & Rubber Feet

**Good news!** The electronics part of the project is now... done!

At this point you can, if you like, put batteries in the battery box, switch it on, and make sure that everything is working correctly. (Please make sure the circuit board is resting on a nonconductive surface when you apply power.)

---

**Parts #23 & 24 are molded button key caps**

These six button caps snap onto the large tactile button switches. First, add the four square button caps (angled at 45°) on the left hand side, and then snap the two round ones onto the right-hand buttons. (If necessary for some reason, the caps can be removed by gently prying them off with a small flathead screwdriver.)

---

**Part #25 is a hard urethane rubber foot**

Install these four clear rubber bumpers to the bottom of the circuit board, on flat parts of the board close to the four screw hole locations. (Suggested locations are shown in circles.) These help to keep the plastron in the correct place and reduce its total flexing.

---

Meggy Jr RGB is designed to be mounted and used inside a handle set (case) that protects the circuit board from your fingers, and protects your fingers from the circuit board. Parts #25-27 are mounting hardware for attaching these handles.

Templates to make your own handle sets are available to download at: http://www.evilmadscientist.com/go/meggyjr
Parts #26 & 27 are nylon screws and acorn nuts

These parts are used to attach the upper and lower shell of a handle set. Use no tools with these! Hand tighten, only as much as needed, by turning the acorn nut. Over-tightening could easily crack the plastic of the handle set.

Mounting the handle set

The top shell of the handle set (the carapace) fits neatly over the LED display, with cutouts for the speaker, buttons, and screw holes. Drop the four nylon screws through the screw holes to help index the lower shell.

The lower shell (the plastron) fits on the bottom side with cutouts for the battery box, the battery box wires, as well as the optional ISP connector and power jack. Use the nylon screws from the top side to help guide the lower shell into place, and secure it in place -- gently-- with the nylon acorn nuts.
STEP 16: Mounting the battery box with velcro

Part #28, the last part, is an adhesive Velcro strip

A strip of velcro with high-strength adhesive is provided to attach the battery box to the back side of the Meggy Jr circuit board.

Before adding the Velcro...

1. Test your Meggy Jr to make sure that it’s working correctly,
2. Trim very short the leads of components that stick up where the velcro will go, and
3. Figure out exactly where you’ll be routing the battery box wires.

If you have not shortened the leads from the battery box, you can route them under the velcro as shown to take up some of the slack and provide strain relief.

When you are ready, attach the hook side of the velcro to the battery box— the side without the switch— and the loop side to the circuit board.
STEP 17: Wrapping it up!

Programming Meggy Jr RGB

Meggy Jr RGB can be programmed through the Arduino development environment (available at http://arduino.cc/), for which we recommend using the USB-TTL cable from Step 1.

This cable connects to J2 as shown at right, with the green-wire end to the side marked “GRN” on the circuit board and the black-wire end to the side marked “BLK” on the circuit board. An Arduino environment library with example code is available. Or, if you want to start from scratch, you can start by looking at the circuit diagram and go from there. You must power on Meggy Jr from battery or an external dc power adapter while programming through the USB-TTL cable; that cable does not provide power to Meggy.

The ATmega168 microcontroller can also be programmed through a standard AVR ISP programmer and the AVR-GCC toolchain, if that’s your preferred environment.

To get started, see our guide to programming Meggy Jr:

http://www.evilmadscientist.com/go/meggyjrlib

Need help?

If you encounter difficulty with Meggy Jr RGB in hardware, software, or elsewhere, odds are that somebody knows how to help you out. Your first stop should be the Evil Mad Scientist Laboratories forums:

http://www.evilmadscientist.com/forum/

An open-source project

The hardware and software designs used in this project have been released under an open-source license. For more information, please see:

http://www.evilmadscientist.com/go/meggyjr

Example firmware is available for download, and your code contributions, handle designs, and games are welcome too— we’d love to see what you can do with it! Productive hacking is strongly encouraged. :)

Got pictures?

If you have interesting pictures or video of things built using this kit or the hardware or software designs, we’d love to see them in the Evil Mad Science Auxiliary:

http://www.flickr.com/groups/evilmadscience/
