# Selection of the queries

---

- ◈ used in an industrial case study on quality assessment of models
- ◈ general purpose queries (not domain-specific)
- ◈ different level of expression complexity
- ⇒ 8 queries for the experiment
- ◈ results with different interpretation
- ⇒ 3 queries for the paper

# Selection of the languages

---

- ◈ querying based on model original representation
  - ⇒ Object Constraint Language (OCL)
  - ⇒ EMFT OCL interpreter
- ◈ mapping models to another representation
  - + querying with an appropriate query language
  - ⇒ Prolog (list representation)
  - ⇒ SWI Prolog

# The goal and the method

---

**Goal:** Performance analysis of model querying with two different query evaluation frameworks.

Additionally: observation of aspects typical for individual query languages.

**Method:** a laboratory experiment with

- ◇ one dependent variable:
  - ◇ the evaluation time
- ◇ three independent variables:
  - ◇ model (118 models of different size 1...10000)
  - ◇ query (8/3 different queries)
  - ◇ evaluation frameworks (OCL, Prolog)

# Q1: Overall number of model elements

- ◇ **linear** execution time for both languages
- ◇ **Prolog faster**  $\Leftarrow$  differences in query formulation (much simpler in Prolog)
- ◇ In **Prolog model size was limited**  $\Leftarrow$  restrictions on memory size (of the used interpreter)

# Model loading time

- ◇ **OCL non-linear** time (up to 70s)  $\Leftarrow$  a text to object hierarchy transformation
- ◇ **Prolog linear** time (up to 30s)  $\Leftarrow$  a text to text transformation
- ◇ Influence of model size:
  - ◇ OCL — using swap memory  $\Rightarrow$  slower loading
  - ◇ Prolog — restrictions on memory size  $\Rightarrow$  limitation on model sizes

# Summary

---

- ◆ **Fast querying** of models is important for *comprehension, analysis and improvement of models*.
- ◆ **Fast feedback** is desired for modeling activities performed by *humans* and within *automated* methods.
- ◆ To study the *performance characteristics* of two different querying techniques, OCL and Prolog, we conducted a **laboratory experiment**.
- ◆ We have developed an **experiment environment** to generate UML models, evaluate queries, collect, parse and analyse the results.

# Discussion

---

There are two important issues:

- ◊ the **choice of queries** was not representative
- ◊ the level of **query optimisation** was determined by authors command of the query languages

The evaluation time of queries can be shortened by improvements in their implementation or by their optimisation through an interpreter. We tried to implement queries to achieve good performance and we assumed that this level of optimisation is realistic.

# Results

---

- ◇ A **list representation** of models, as used for Prolog, is more effective for queries collecting or selecting elements based on their **direct properties** (like Q1).
- ◇ A **hierarchical representation** (reflecting original structure) of models together with navigation abilities of a query language, as in case of OCL, enables faster evaluation of queries based on properties of **relationships between elements** (like Q2).

## Future work

---

- ◈ Studies on *performance and expressiveness* of both languages could provide **application guidelines** for OCL and Prolog queries in model analysis.
- ◈ Such guidelines could help tool vendors to decide which representation and evaluation of models and queries is better suited for **types of analysis** to be implemented.

# Queries in the experiment

---

1. overall number of model elements (measure for model size)
2. list of all classes that have exactly two associations
3. maximal depth of the inheritance tree
4. ratio of abstract classes (measure for abstractness of the model)
5. number of associations (measure for associativity of the model)
6. class with a specific name
7. list of instances(objects) of a specific class
8. list of all classes that have association to a specific class
