Chapter 9 Objects and Classes

CS1: Java Programming
Colorado State University

Original slides by Daniel Liang
Modified slides by Chris Wilcox
Classes

*Classes* are constructs that define objects of the same type. A Java class uses variables to define data fields and methods to define behaviors. Additionally, a class provides a special type of methods, known as constructors, which are invoked to construct objects from the class.
class Circle {
    /** The radius of this circle */
    double radius = 1.0;

    /** Construct a circle object */
    Circle() {
    }

    /** Construct a circle object */
    Circle(double newRadius) {
        radius = newRadius;
    }

    /** Return the area of this circle */
    double getArea() {
        return radius * radius * 3.14159;
    }
}
UML Class Diagram

Class name

Data fields

Constructors and methods

<table>
<thead>
<tr>
<th>Circle</th>
</tr>
</thead>
<tbody>
<tr>
<td>radius: double</td>
</tr>
<tr>
<td>Circle()</td>
</tr>
<tr>
<td>Circle(newRadius: double)</td>
</tr>
<tr>
<td>getArea(): double</td>
</tr>
<tr>
<td>getPerimeter(): double</td>
</tr>
<tr>
<td>setRadius(newRadius: double): void</td>
</tr>
</tbody>
</table>

UML notation for objects

<table>
<thead>
<tr>
<th>circle1: Circle</th>
</tr>
</thead>
<tbody>
<tr>
<td>radius = 1.0</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>circle2: Circle</th>
</tr>
</thead>
<tbody>
<tr>
<td>radius = 25</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>circle3: Circle</th>
</tr>
</thead>
<tbody>
<tr>
<td>radius = 125</td>
</tr>
</tbody>
</table>
Constructors

Constructors are a special kind of methods that are invoked to construct objects.

```java
Circle() {
}

Circle(double newRadius) {
    radius = newRadius;
}
```
Constructors, cont.

A constructor with no parameters is referred to as a no-arg constructor.

- Constructors must have the same name as the class itself.
- Constructors do not have a return type—not even void.
- Constructors are invoked using the new operator when an object is created. Constructors play the role of initializing objects.
Default Constructor

A class may be defined without constructors. In this case, a no-arg constructor with an empty body is implicitly defined in the class. This constructor, called a default constructor, is provided automatically only if no constructors are explicitly defined in the class.
Declaring Object Reference Variables

To reference an object, assign the object to a reference variable.

To declare a reference variable, use the syntax:

```
ClassName objectRefVar;
```

Example:

```
Circle myCircle;
```
Trace Code

```java
Circle myCircle = new Circle(5.0);

Circle yourCircle = new Circle();

yourCircle.radius = 100;
```

Declare myCircle

myCircle no value
Trace Code, cont.

Circle myCircle = new Circle(5.0);

Circle yourCircle = new Circle();

yourCircle.radius = 100;
Circle myCircle = new Circle(5.0);

Circle yourCircle = new Circle();

yourCircle.radius = 100;

Assign object reference to myCircle
Trace Code, cont.

Circle myCircle = new Circle(5.0);

Circle yourCircle = new Circle();

yourCircle.radius = 1.0;
Trace Code, cont.

Circle myCircle = new Circle(5.0);

Circle yourCircle = new Circle();

yourCircle.radius = 1.0;
Circle myCircle = new Circle(5.0);

Circle yourCircle = new Circle();

yourCircle.radius = 1.0;
Reference Data Fields

The data fields can be of reference types. For example, the following Student class contains a data field name of the String type.

```java
public class Student {
    String name; // name has default value null
    int age; // age has default value 0
    boolean isScienceMajor; // isScienceMajor has default value false
    char gender; // c has default value '\u0000'
}
```
The null Value

If a data field of a reference type does not reference any object, the data field holds a special literal value, null.
Garbage Collection

When an object is no longer referenced, it becomes “garbage”.

Garbage is automatically collected by JVM.
Instance variables belong to a specific instance.

Instance methods are invoked by an instance of the class.

Instance variables and methods are specified by omitting the `static` keyword.
Static Variables, Constants, and Methods

Static variables are shared by all the instances of the class.

Static methods are not tied to a specific object.

Static constants are final variables shared by all the instances of the class.

To declare static variables, constants, and methods, use the static modifier.
Example of Using Instance and Class Variables and Method

Objective: Demonstrate the roles of instance and class variables and their uses. This example adds a class variable numberOfObjects to track the number of Circle objects created.
Visibility Modifiers and Accessor/Mutator Methods

By default, the class, variable, or method can be accessed by any class in the same package.

- **public**
  The class, data, or method is visible to any class in any package.

- **private**
  The data or methods can be accessed only by the declaring class.

The get and set methods are used to read and modify private properties.
Passing Objects to Methods

- Passing by value for primitive type value (the value is passed to the parameter)
- Passing by value for reference type value (the value is the reference to the object)
The this Keyword

- The `this` keyword is the name of a reference that refers to an object itself. One common use of the `this` keyword is reference a class’s *hidden data fields*.

- Another common use of the `this` keyword to enable a constructor to invoke another constructor of the same class.
Reference instance variables

public class F {
    private int i = 5;
    private static double k = 0;

    void setI(int i) {
        this.i = i;
    }

    static void setK(double k) {
        F.k = k;
    }
}

Suppose that f1 and f2 are two objects of F.
F f1 = new F(); F f2 = new F();

Invoking f1.setI(10) is to execute
    this.i = 10, where this refers f1

Invoking f2.setI(45) is to execute
    this.i = 45, where this refers f2
public class Circle {
  private double radius;

  public Circle(double radius) {
    this.radius = radius;
  }

  public Circle() {
    this(1.0);
  }

  public double getArea() {
    return this.radius * this.radius * Math.PI;
  }

}  

Every instance variable belongs to an instance represented by this, which is normally omitted

this must be explicitly used to reference the data field radius of the object being constructed

this is used to invoke another constructor
