- Various sources
Multiprogramming, Multitasking, Multiprocessing

- **Multiprogramming**: multiple program under execution at the same time, switching programs when needed (older term)
- **Timesharing (multitasking)**: sharing a CPU among multiple users using time slicing (older term). *Multitasking among people* ...
- **Multiprocessing**: multiple processors in the system running in parallel.
- **Program vs process**: a program under execution can constitute one or more processes.
- **Job**: (older, somewhat ambiguous term) an executing program or a process.
Memory Layout for Multiprogrammed System

Multiprocessors

• Past systems used a single general-purpose processor
  – Most systems have special-purpose processors as well
• **Multiprocessors** systems were once special, now are common
  – Advantages include:
    1. Increased throughput
    2. Economy of scale
    3. Increased reliability – graceful degradation or fault tolerance
  – Two types:
    1. **Asymmetric Multiprocessing** – each processor is assigned a specific task.
    2. **Symmetric Multiprocessing** – each processor performs all tasks
Symmetric Multiprocessing Architecture

Multiprocessor

Multi-chip and multicore

• Multi-chip: Systems containing all chips
  – Chassis containing multiple separate systems

• Multi-core
• **Dual-mode** operation allows OS to protect itself and other system components

  – **User mode** and **kernel mode**
  – **Mode bit** provided by hardware
    • Provides ability to distinguish when system is running user code or kernel code
    • Some instructions designated as **privileged**, only executable in kernel mode
    • System call changes mode to kernel, return from call resets it to user

• Increasingly CPUs support multi-mode operations
  – i.e. **virtual machine manager (VMM)** mode for guest **VMs**

  called Supervisor mode in LC3 processor in P&P book
Transition from User to Kernel Mode

• Timer to prevent a process from hogging resources
  – Timer is set to interrupt the computer after some time period
  – Keep a counter that is decremented by the physical clock.
  – Operating system set the counter (privileged instruction)
  – When counter zero generate an interrupt
  – Set up before scheduling process to regain control or terminate program that exceeds allotted time

• System calls are executed in the kernel mode
Process Management

- A process is a program in execution. It is a unit of work within the system. Program is a *passive entity*, process is an *active entity*.
- Process needs resources to accomplish its task
  - CPU, memory, I/O, files
  - Initialization data
- Process termination requires reclaim of any reusable resources
- **Single-threaded process** has one *program counter* specifying location of next instruction to execute
  - Process executes instructions sequentially, one at a time, until completion
- **Multi-threaded process** has one program counter per thread
- Typically system has many processes (some user, some operating system), running concurrently on one or more CPUs
  - Concurrency by multiplexing the CPUs among the processes / threads
Process Management Activities

The operating system is responsible for the following activities in connection with process management:

• Creating and deleting both user and system processes
• Suspending and resuming processes
• Providing mechanisms for
  – process synchronization
  – process communication
  – deadlock handling
Memory & Storage Management
K-scale: Amount of information/storage

Byte (B) = 8 bits (b)

- A kilobyte, or KB, is $1,024$ (or $2^{10}$) bytes
- a megabyte, or MB, is $1,024^2$ (or $2^{20}$) bytes
- a gigabyte, or GB, is $1,024^3$ bytes
- a terabyte, or TB, is $1,024^4$ bytes
- a petabyte, or PB, is $1,024^5$ bytes
Memory Management

• To execute a program all (or part) of the instructions must be in memory.
• All (or part) of the data that is needed by the program must be in memory.
• Memory management determines what is in memory and when
  – Optimizing CPU utilization and computer response to users
• Memory management activities
  – Keeping track of which parts of memory are currently being used and by whom
  – Deciding which processes (or parts thereof) and data to move into and out of memory
  – Allocating and deallocating memory space as needed
Storage Management

• OS provides uniform, logical view of information storage
  – Abstracts physical properties to logical storage unit - file
  – Each medium is controlled by device (i.e., disk drive, tape drive)
    • Varying properties include access speed, capacity, data-transfer rate, access method (sequential or random)

• File-System management
  – Files usually organized into directories
  – Access control on most systems to determine who can access what
  – OS activities include
    • Creating and deleting files and directories
    • Primitives to manipulate files and directories
    • Mapping files onto secondary storage
    • Backup files onto stable (non-volatile) storage media
Mass-Storage Management

• Usually disks used to store data that does not fit in main memory or data that must be kept for a “long” period of time
• Entire speed of computer operation hinges on disk subsystem and its algorithms
• OS activities
  – Free-space management
  – Storage allocation
  – Disk scheduling
• Some storage need not be fast
  – Tertiary storage includes optical storage, magnetic tape
  – Still must be managed – by OS or applications
  – Varies between WORM (write-once, read-many-times) and RW (read-write)
Migration of data “A” from Disk to Register

- Multitasking environments must be careful to use most recent value, no matter where it is stored in the storage hierarchy

- Multiprocessor environment must provide *cache coherency* in hardware such that all CPUs have the most recent value in their cache

- Distributed environment situation even more complex
  - Several copies of a datum can exist
  - Various solutions covered in Chapter 19 *(will not get to it)*

Spring 2019 OS Structures

Slides based on
• Text by Silberschatz, Galvin, Gagne
• Various sources
Objectives:

• Services OS provides to users, processes, and other systems
• Structuring an operating system
• How operating systems are designed and customized and how they boot
• Operating systems provide an environment for execution of programs and services to programs and users
  
  – **User interface** - Almost all operating systems have a user interface (UI).
    
    • Varies between **Command-Line (CLI)**, **Graphics User Interface (GUI)**, **Batch**
  
  – **Program execution** - The system must be able to load a program into memory and to run that program, end execution, either normally or abnormally (indicating error)
  
  – **I/O operations** - A running program may require I/O, which may involve a file or an I/O device
– **File-system operations** - read and write files and directories, create and delete them, search them, list file information, permission management.

– **Communications** – Processes may exchange information, on the same computer or between computers over a network
  
  • via shared memory or through message passing (packets moved by the OS)

– **Error detection** – OS needs to be constantly aware of possible errors
  
  • May occur in the CPU and memory hardware, in I/O devices, in user program
  
  • For each type of error, OS should take the appropriate action to ensure correct and consistent computing
OS services for system 3/3 (Cont.)

- OS functions for ensuring the efficient resource sharing
  - **Resource allocation** - When multiple users or multiple jobs running concurrently, resources must be allocated to each of them
    - Many types of resources - CPU cycles, main memory, file storage, I/O devices.
  - **Accounting** - To keep track of which users use how much and what kinds of computer resources
  - **Protection and security** - Concurrent processes should not interfere with each other
    - **Protection** involves ensuring that all access to system resources is controlled
    - **Security** of the system from outsiders requires user authentication, extends to defending external I/O devices from invalid access attempts
A View of Operating System Services

user and other system programs

services

operating system

hardware
CLI or **command interpreter** allows direct command entry

- Sometimes implemented in kernel, sometimes by systems program
- Sometimes multiple flavors implemented – **shells**
- Primarily fetches a command from user and executes it
- Sometimes commands built-in, sometimes just names of programs
  - If the latter, adding new features doesn’t require shell modification

**Ex:**
Windows: command prompt
Linux: bash
Shell Command Interpreter

</table>
User-friendly **desktop** metaphor interface

- Usually mouse, keyboard, and monitor
- **Icons** represent files, programs, actions, etc
- Various mouse buttons over objects in the interface cause various actions (provide information, options, execute function, open directory (known as a **folder**))
- Invented at Xerox PARC in 1973

**Most systems now include both CLI and GUI interfaces**

- Microsoft Windows is GUI with CLI “command” shell
- Apple Mac OS X is “Aqua” GUI interface with UNIX kernel underneath and shells available
- Unix and Linux have CLI with optional GUI interfaces (CDE, KDE, GNOME)
Touchscreen Interfaces

• Touchscreen devices require new interfaces
  • Mouse not possible or not desired
  • Actions and selection based on gestures
  • Virtual keyboard for text entry
  • Voice commands.
The Mac OS X GUI
**System Calls**

- Programming interface to the services provided by the OS
- Typically written in a high-level language (C or C++)
- Mostly accessed by programs via a high-level **Application Programming Interface (API)** rather than direct system call use
- Three most common APIs are Win32 API for Windows, POSIX API for POSIX-based systems (including virtually all versions of UNIX, Linux, and Mac OS X), and Java API for the Java virtual machine (JVM)

Note that the system-call names used throughout our text are generic
Example of System Calls

- System call sequence to copy the contents of one file to another file

Example System Call Sequence:
- Acquire input file name
- Write prompt to screen
- Accept input
- Acquire output file name
- Write prompt to screen
- Accept input
- Open the input file
  - if file doesn't exist, abort
- Create output file
  - if file exists, abort
- Loop
  - Read from input file
  - Write to output file
  - Until read fails
- Close output file
- Write completion message to screen
- Terminate normally
Example of Standard API

As an example of a standard API, consider the `read()` function that is available in UNIX and Linux systems. The API for this function is obtained from the `man` page by invoking the command

```
man read
```
on the command line. A description of this API appears below:

```
#include <unistd.h>

ssize_t read(int fd, void *buf, size_t count)
```

A program that uses the `read()` function must include the `unistd.h` header file, as this file defines the `ssize_t` and `size_t` data types (among other things). The parameters passed to `read()` are as follows:

- `int fd` — the file descriptor to be read
- `void *buf` — a buffer where the data will be read into
- `size_t count` — the maximum number of bytes to be read into the buffer

On a successful read, the number of bytes read is returned. A return value of 0 indicates end of file. If an error occurs, `read()` returns -1.

`unistd.h` header file provides access to the POSIX API.
System Call Implementation

• The caller need know nothing about how the system call is implemented
  – Just needs to obey API and understand what OS will do as a result call
  – Most details of OS interface hidden from programmer by API
    • Managed by run-time support library (set of functions built into libraries included with compiler)

• System call implementation examples:
  – LC-3 Trap x21 (OUT) code in Patt & Patel
  – Identified by a number that leads to address of the routine
  – Arguments provided in designated registers
  – Linux x86_64 table

</table>
Standard C Library Example

- C program invoking `printf() library call`, which calls `write() system call`
- Single-tasking
- Shell invoked when system booted
  - No process created
- Single memory space
- Loads program into memory, overwriting all but the kernel
- Program exit -> shell reloaded

At system startup

running a program
Example: xBSD '93 Berkely

- Unix '73 variant, inherited by several later OSs
- Multitasking
- User login -> invoke user’s choice of shell
- Shell executes fork() system call to create process
  - Executes exec() to load program into process
  - Shell waits for process to terminate or continues with user commands
- Process exits with:
  - code = 0 – no error
  - code > 0 – error code
