CS 370: OPERATING SYSTEMS
[DEADLOCKS]

Shrideep Pallickara
Computer Science
Colorado State University

Frequently asked questions from the previous class survey

- Prevention or avoidance: Which is better?
- Delay durations when "stalling" requests: how long is too long?

Topics covered in this lecture

- Deadlock Avoidance
  - Banker's Algorithm
- Deadlock Detection
  - And … recovery
- Other issues relating to deadlocks

A deadlock-prone system can be in one of three states: safe, unsafe, and deadlocked

- Safe state: For any possible sequence of resource requests, there is **at least one safe sequence** of processing the requests
  - That eventually succeeds in **granting** all pending and future requests
- Unsafe state: There is *at least one sequence* of future resource requests that leads to deadlock
- In a deadlocked state, the system has at least one deadlock

A system in a safe state controls its own destiny

- For any workload, it can avoid deadlock by delaying the processing of some requests
  - Once the system enters an unsafe state, it may not be able to avoid deadlock
- In particular, the Banker's Algorithm (that we will look at next) **delays** any request that takes it from a safe to an unsafe state.

BANKER'S ALGORITHM

Banker's Algorithm

- Designed by Dijkstra in 1965
- Modeled on a small-town banker
  - Customers have been extended lines of credit
  - Not ALL customers will need their maximum credit immediately
- Customers make loan requests from time to time

Crux of the Banker's Algorithm

- Consider each request as it occurs
  - See if granting it is safe
- If safe: grant it; If unsafe: postpone
- For safety banker checks if he/she has **enough** to satisfy some customer
  - If so, that customer's loans are assumed to be repaid
  - Customer closest to limit is checked next
  - **If all loans can be repaid; state is safe: loan approved**

Banker's Algorithm: Managing the customers. Banker has only reserved 10 units instead of 22

	Has	Max
A	0	6
B	0	5
C	0	4
D	0	7

Free: 10

SAFE

	Has	Max
A	1	6
B	1	5
C	2	4
D	4	7

Free: 2

Delay all requests except C

SAFE

	Has	Max
A	1	6
B	2	5
C	2	4
D	4	7

Free: 1

UNSAFE

A customer may not need the entire credit line. But the banker cannot count on this behavior

There is ONLY ONE resource -- Credit

Banker's algorithm: Crux

- Declare **maximum** number of resource instances needed
  - Cannot exceed resource thresholds
- Determine if resource allocations leave system in a safe state

Bankers Algorithm: Data Structures [Overview]

	Allocation			Max			Available		
	A	**B**	**C**	**A**	**B**	**C**	**A**	**B**	**C**
P0	0	1	0	7	5	3	3	3	2
P1	2	0	0	3	2	2			
P2	3	0	2	9	0	2			
P3	2	1	1	2	2	2			
P4	0	0	2	4	3	3			

A, **B**, and **C** are different *types* of resources

Data Structures: **n** is the number of processes and **m** is the number of resource types

- `Available`: Vector of length `m`
  - Number of resources for each type
    - `Available[i] = k`
- `Max`: `n` x `m` matrix
  - Maximum *demand* for each process (in each row)
  - `Max[i,j]= k`
    - Process P_i may request at most `k` instances of R_j

Data Structures: n is the number of processes and m is the number of resource types

- Allocation: n x m matrix
  - Resource instances allocated for each process (each row)
  - Allocation[i,j]=k
    - Process P_i currently **allocated** k instances of R_j
- Need: n x m matrix
  - Resource instances needed for each process (each row)
  - Need[i,j]=k
    - Process P_i *may need* k **more** instances of R_j

Vectors identifying a process' resource requirements: Rows in the matrices

- $Allocation_i$
  - Resource instances allocated for process P_i
- $Need_i$
  - Additional resource instances that process P_i may still request

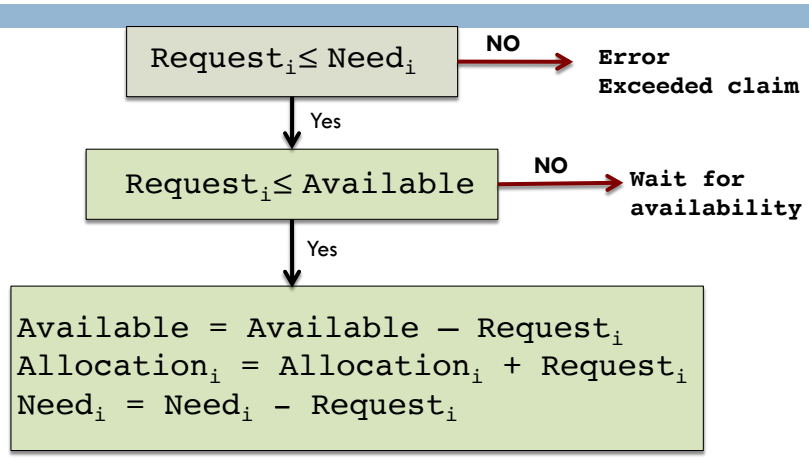
Banker's Algorithm: Notations

- **X** and **Y** are vectors of length m
- **X** ≤ **Y** if-and-only-if
  X[i] ≤ **Y**[i] *for all* i=1,2,...,m
- **X** = {1,7,3,2} and **Y** = {0,3,2,1}
  So, **Y** ≤ **X**
  Also **Y** < **X** if **Y** ≤ **X** and **Y** ≠ **X**

Banker's Algorithm: Resource-request

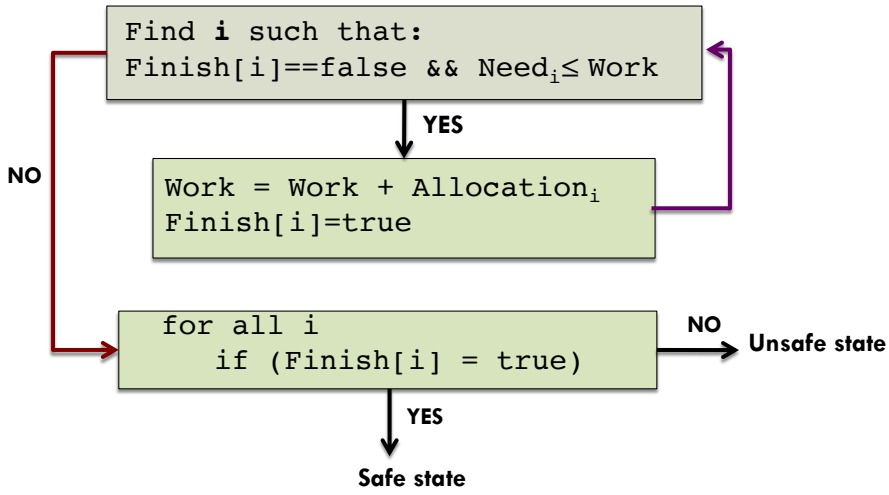
- $Request_i$: Request vector for process P_i
  - $Request_i[j]=k$
    - Process P_i wants k instances of R_j

Bankers Algorithm: Resource-request



Bankers Algorithm: Safety

Initialize Work = Available



Bankers Algorithm: Example

	Allocation			Max			Available		
	A	**B**	**C**	**A**	**B**	**C**	**A**	**B**	**C**
P0	0	1	0	7	5	3	3	3	2
P1	2	0	0	3	2	2			
P2	3	0	2	9	0	2			
P3	2	1	1	2	2	2			
P4	0	0	2	4	3	3			

<P1, P3, P4, P2, P0> satisfies safety criteria

Suppose process **P1** requests 1 **A**, and 2 **C**s: $\texttt{Request}_1$ = (1,0,2)

$\texttt{Request}_1 \leq$ Available

Pretend request was fulfilled

Bankers Algorithm: Example

	Allocation			Max			Available		
	A	**B**	**C**	**A**	**B**	**C**	**A**	**B**	**C**
P0	0	1	0	7	5	3	2	3	0
P1	3	0	2	3	2	2			
P2	3	0	2	9	0	2			
P3	2	1	1	2	2	2			
P4	0	0	2	4	3	3			

<P1, P3, P4, P0, P2> satisfies safety criteria

$\texttt{Request}_4$ = (3,3,0) from process **P4** cannot be granted: resources unavailable

$\texttt{Request}_0$ = (0,2,0) from process **P0** cannot be granted: unsafe state

Bankers Algorithm: Example

	Allocation			Max			Available		
	A	**B**	**C**	**A**	**B**	**C**	**A**	**B**	**C**
P0	0	3	0	7	3	3	2	1	0
P1	3	0	2	3	2	2			
P2	3	0	2	9	0	2			
P3	2	1	1	2	2	2			
P4	0	0	2	4	3	3			

None of the processes can now satisfy their max resource needs.

$\texttt{Request}_0$ = (0,2,0) from process **P0** cannot be granted: unsafe state

Bankers Algorithm: Practical implications [1/2]

- Understanding the Banker's Algorithm can help in designing simple solutions for specific problems
- Banker's Algorithm to devise a rule for thread safe acquisition of a pair of locks, **A** and **B**, with **mutually recursive** locking?
  - Suppose a thread needs to acquire locks **A** and **B**, in that order, while another thread needs to acquire lock **B** first, then **A**
  - RULE: A thread is always allowed to acquire its second lock
    - Acquire first lock provided the other thread does not already hold its first lock

Bankers Algorithm: Practical implications [2/2]

- Processes *rarely know in advance* about their maximum resource needs
- Number of processes managed by the kernel is not fixed
  - Varies dynamically
- Resources thought to be available can vanish

DEADLOCK DETECTION

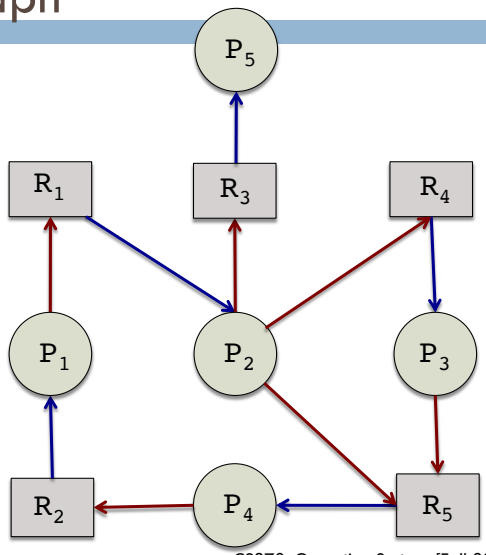
Single instance of EACH resource type

- Use **wait-for** graph
  - *Variant* of the resource allocation graph
- Deadlock exists if there is a **cycle** in the graph
- Transformation
  1. **Remove** resource nodes
  2. **Collapse** appropriate edges

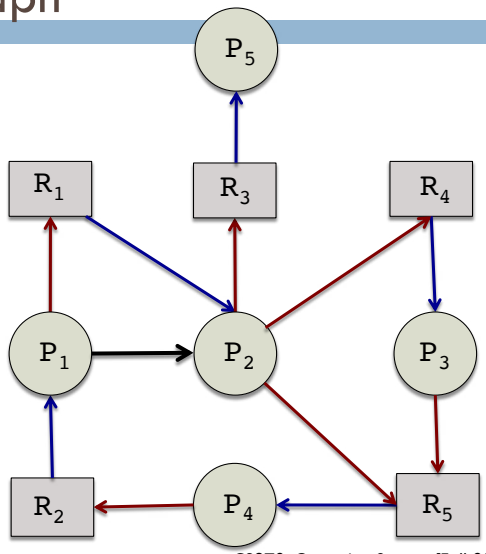
What the edges in the wait-for graph imply

- $P_i \rightarrow P_j$
  - Process P_i is waiting for a resource held by P_j
- $P_i \rightarrow P_j$ only if resource allocation graph has
  1. $P_i \rightarrow R_q$ and
  2. $R_q \rightarrow P_j$ for some resource R_q

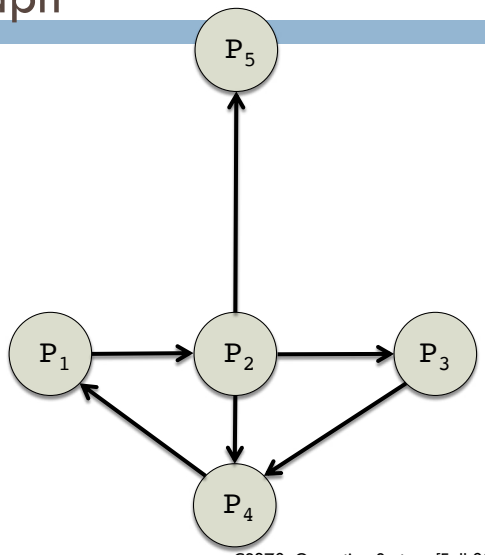
Transforming a resource allocation graph into a wait-for graph



Transforming a resource allocation graph into a wait-for graph



Transforming a resource allocation graph into a wait-for graph



Deadlock detection for multiple instances of a resource type

- Wait-for graph is not applicable
- Approach uses data structures similar to Banker's algorithm

Data Structures: n is number of processes m is number of resource types

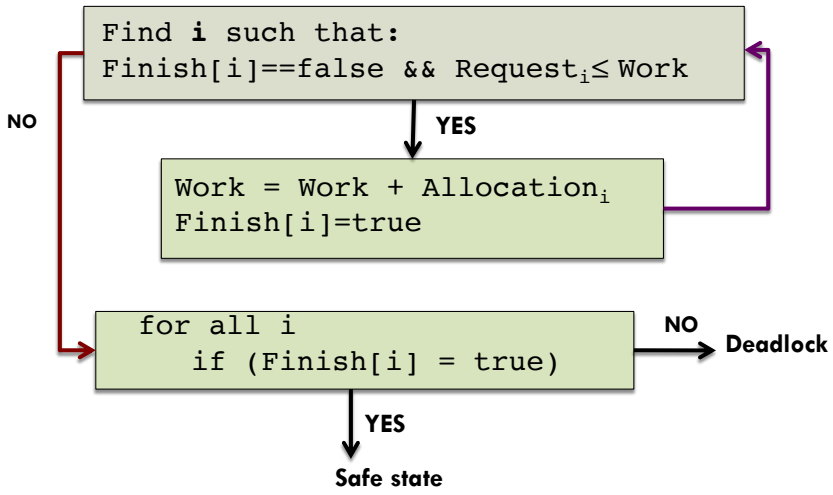
- `Available`: Vector of length `m`
  - Number of resources for each type
- `Allocation`: `n` x `m` matrix
  - Resource instances allocated for each process
  - `Allocation[i,j]=k`
    - Process P_i currently **allocated** `k` instances of R_j
- `Request`: `n` x `m` matrix
  - Current request for each process
  - `Request[i,j]=k`
    - Process P_i **requests** `k` **more** instances of R_j

Deadlock detection: Initialization

`Work` and `Finish` are vectors of length `m` & `n`

```
Work = Available
if (Allocation_i ≠ 0) {
  Finish[i] = false;
} else {
  Finish[i] = true;
}
```

Deadlock detection



Deadlock detection: Usage

- How **often** will the deadlock occur?
- How **many** processes will be affected when it happens?

Frequency of invoking deadlock detection

- Resources allocated to deadlocked process **idle**
  - Until the deadlock can be broken
- Deadlocks occur *only* when process makes a request
  - Significant overheads to run detection per request
- Middle ground: Run at *regular intervals*

RECOVERY FROM DEADLOCK

Recovery from deadlock

- Automated or manual
- OPTIONS
  - Break the circular wait: **Abort processes**
  - **Preempt** resources from deadlocked process(es)

Breaking circular wait: Process termination

- Abort **all** deadlocked processes
- Abort processes **one at a time**
  - After each termination, check if deadlock *persists*
- Reclaim all resources allocated to terminated process

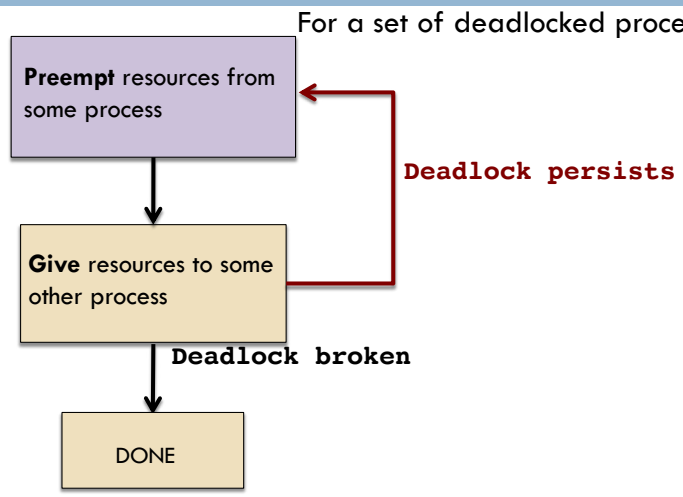
Terminating a Process

- Process may be in the midst of something
  - Updating files, printing data, etc.
- Abort process whose termination will incur **minimum** costs
  - Policy decision similar to scheduling decisions

Factors determining process termination

- Priority
- How long has the process been running?
  - How much longer?
- Number and types of resources used
  - How many more needed?
- Interactive or batch

Deadlock recovery: Resource preemption



Resource preemption: Issues

- Selecting a victim
  - Which resource and process
  - Order of preemption to minimize cost
- Starvation
  - Process can be selected for preemption *finite* number of times

Deadlock recovery through rollbacks

- **Checkpoint** process periodically
  - Contains memory image and resource state
- Deadlock detection tells us *which* resources are needed
- Process owning a needed resource
  - **Rolled back** to before it acquired needed resource
    - Work done since rolled back checkpoint discarded
  - **Assign** resource to deadlocked process

OTHER ISSUES

Two-phase locking

- Used in database systems
- Operation involves requesting locks on several records and updating all the locked records
- When multiple processes are running?
  - Possibility of deadlocks

Two-Phase Locking

- First phase
  - Process tries to acquire all the locks it needs, one at time
  - If successful: start second-phase
  - If some record is already locked?
    - Release all locks and start the first phase all over
- Second-phase
  - Perform updates and release the locks

Communication Deadlocks

- Process **A** sends a request message to process **B**
  - Blocks until **B** sends a reply back
- Suppose, that the request was lost
  - **A** is blocked waiting for a reply
  - **B** is blocked waiting for a request to do something
  - **Communication deadlock**

Communication deadlocks

- Cannot be prevented by ordering resources (there are none)
  - Or avoided by careful scheduling (no moments when a request can be postponed)
- Solution to breaking communication deadlocks?
  - **Timeouts**
    - Start a timer when you send a message to which a reply is expected.

Livelocks

- Polling (busy waits) used to enter critical section or access a resource
  - Typically used for a short time when overhead for suspension is considered greater
- In a livelock two processes need each other's resource
  - Both run and make no progress, but neither process blocks
  - **Use CPU quantum over and over without making progress**

Livelocks do occur

- If fork fails because process table is full
  - Wait for some time and try again
- But there could be a collection of processes each trying to do the same thing
